

USER INTERFACE TECHNIQUE FOR SELECTION AND ACTIVATION OF
WIRELESS SERVICES FROM AMONG MULTIPLE TRANSPORT CARRIERS

ABSTRACT

5

A method and device are provided for handling network
activation between a computer and a carrier. In one example,
the method involves receiving a command to initiate network
activation procedures. The network activation status of the
10 computer is then determined. If the computer is network
enabled, a request is sent to a device having network
activation information. The network activation information is
received from the device. The computer is then configured
with the network activation information in order to establish
15 network activation with the carrier.
